

# AGNesF: Adaptive Gaussian Nested Filter for Parameter Estimation and State Tracking in Dynamical Systems

## Background: nested methodology

**Goal:** Computation of the joint posterior pdf

$$p(\theta, x_t | y_{1:t}) = \underbrace{p(x_t | \theta, y_{1:t})}_{\text{bottom layer}} \times \underbrace{p(\theta | y_{1:t})}_{\text{top layer}}$$

- $\theta$  are static parameters
- $x_t$  is a dynamic state variable

**Structure:**

**Top layer:  $\theta$  estimation.**

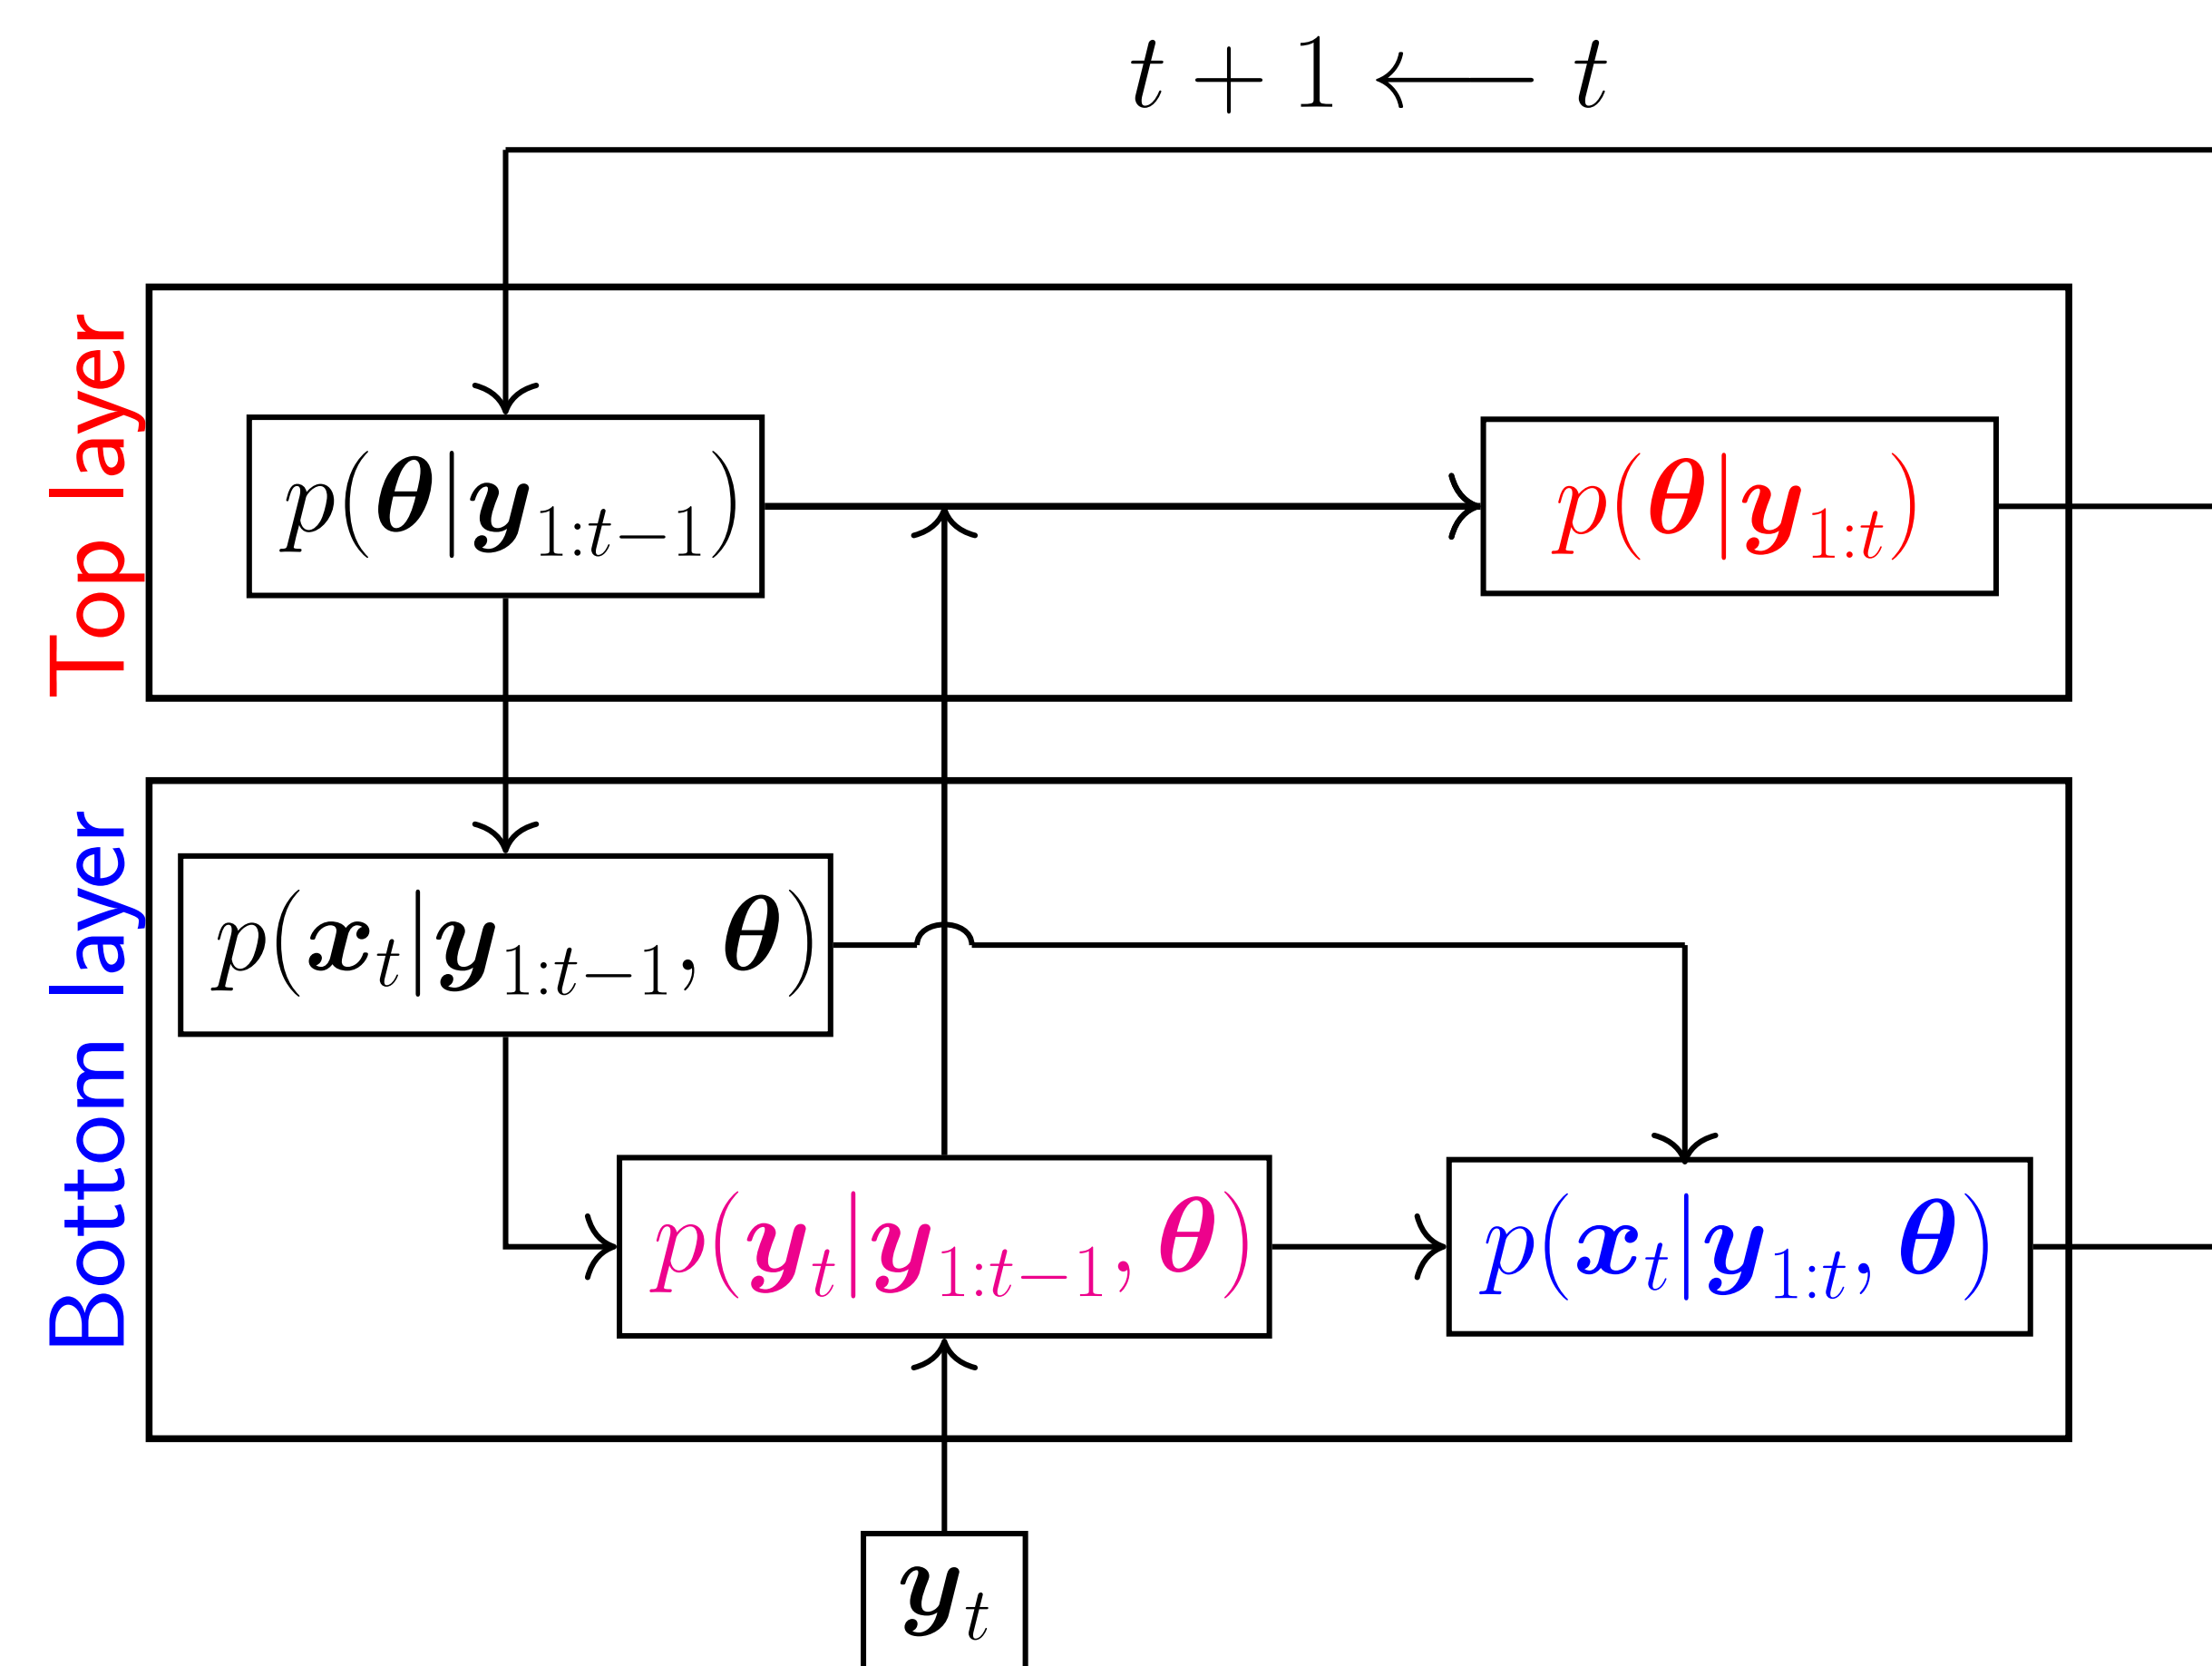

- Use of sampling filtering techniques, e.g., SMC, SQMC, UKF, QKF.
- $p(\theta | y_{1:t})$  is represented with  $\{\theta_t^i, w_t^i\}_{i=1}^{N_\theta}$ .

**Bottom layer:  $x$  tracking.**

- Use of any filtering technique, e.g., SMC, EKF, UKF.
- Implementation of  $N_\theta$  filters (one for each  $\theta_t^i$ ).

**Key point: likelihood computation.**

- $p(y_t | y_{1:t-1}, \theta)$  needs to be computed in the bottom layer.

## Objective and approach

**Objective:**

- **Reduce computational complexity** of nested Gaussian filters without compromising performance.

**Approach:**

- **Reduce the number of points**,  $N_\theta$ , when parameters are close to convergence.
- Decision based on an **adaptive rule**.

## The statistic $\rho_t$

**The statistic,  $\rho_t$ :**

$$\rho_t = \frac{1}{\sum_{n=1}^{N_{\theta,t}} (\bar{s}_t^n)^2} \quad \text{with} \quad \bar{s}_t^n = \frac{p(y_t | y_{1:t-1}, \theta_t^n)}{\sum_{n=1}^{N_{\theta,t}} p(y_t | y_{1:t-1}, \theta_t^n)}$$

- It takes its **minimum value** in  $\rho_t = 1$ , when only one  $p(y_t | y_{1:t-1}, \theta_t^n)$  is different from zero.
- It takes its **maximum value** in  $\rho_t = N_{\theta,t}$ , when for all the evaluations  $p(y_t | y_{1:t-1}, \theta_t^n)$  are equal.

## Adaptive rule

**Fixed  $N_\theta$ .** Using a QKF in the top layer,  $N_\theta$  is computed as

$$N_\theta = \alpha^{d_\theta}.$$

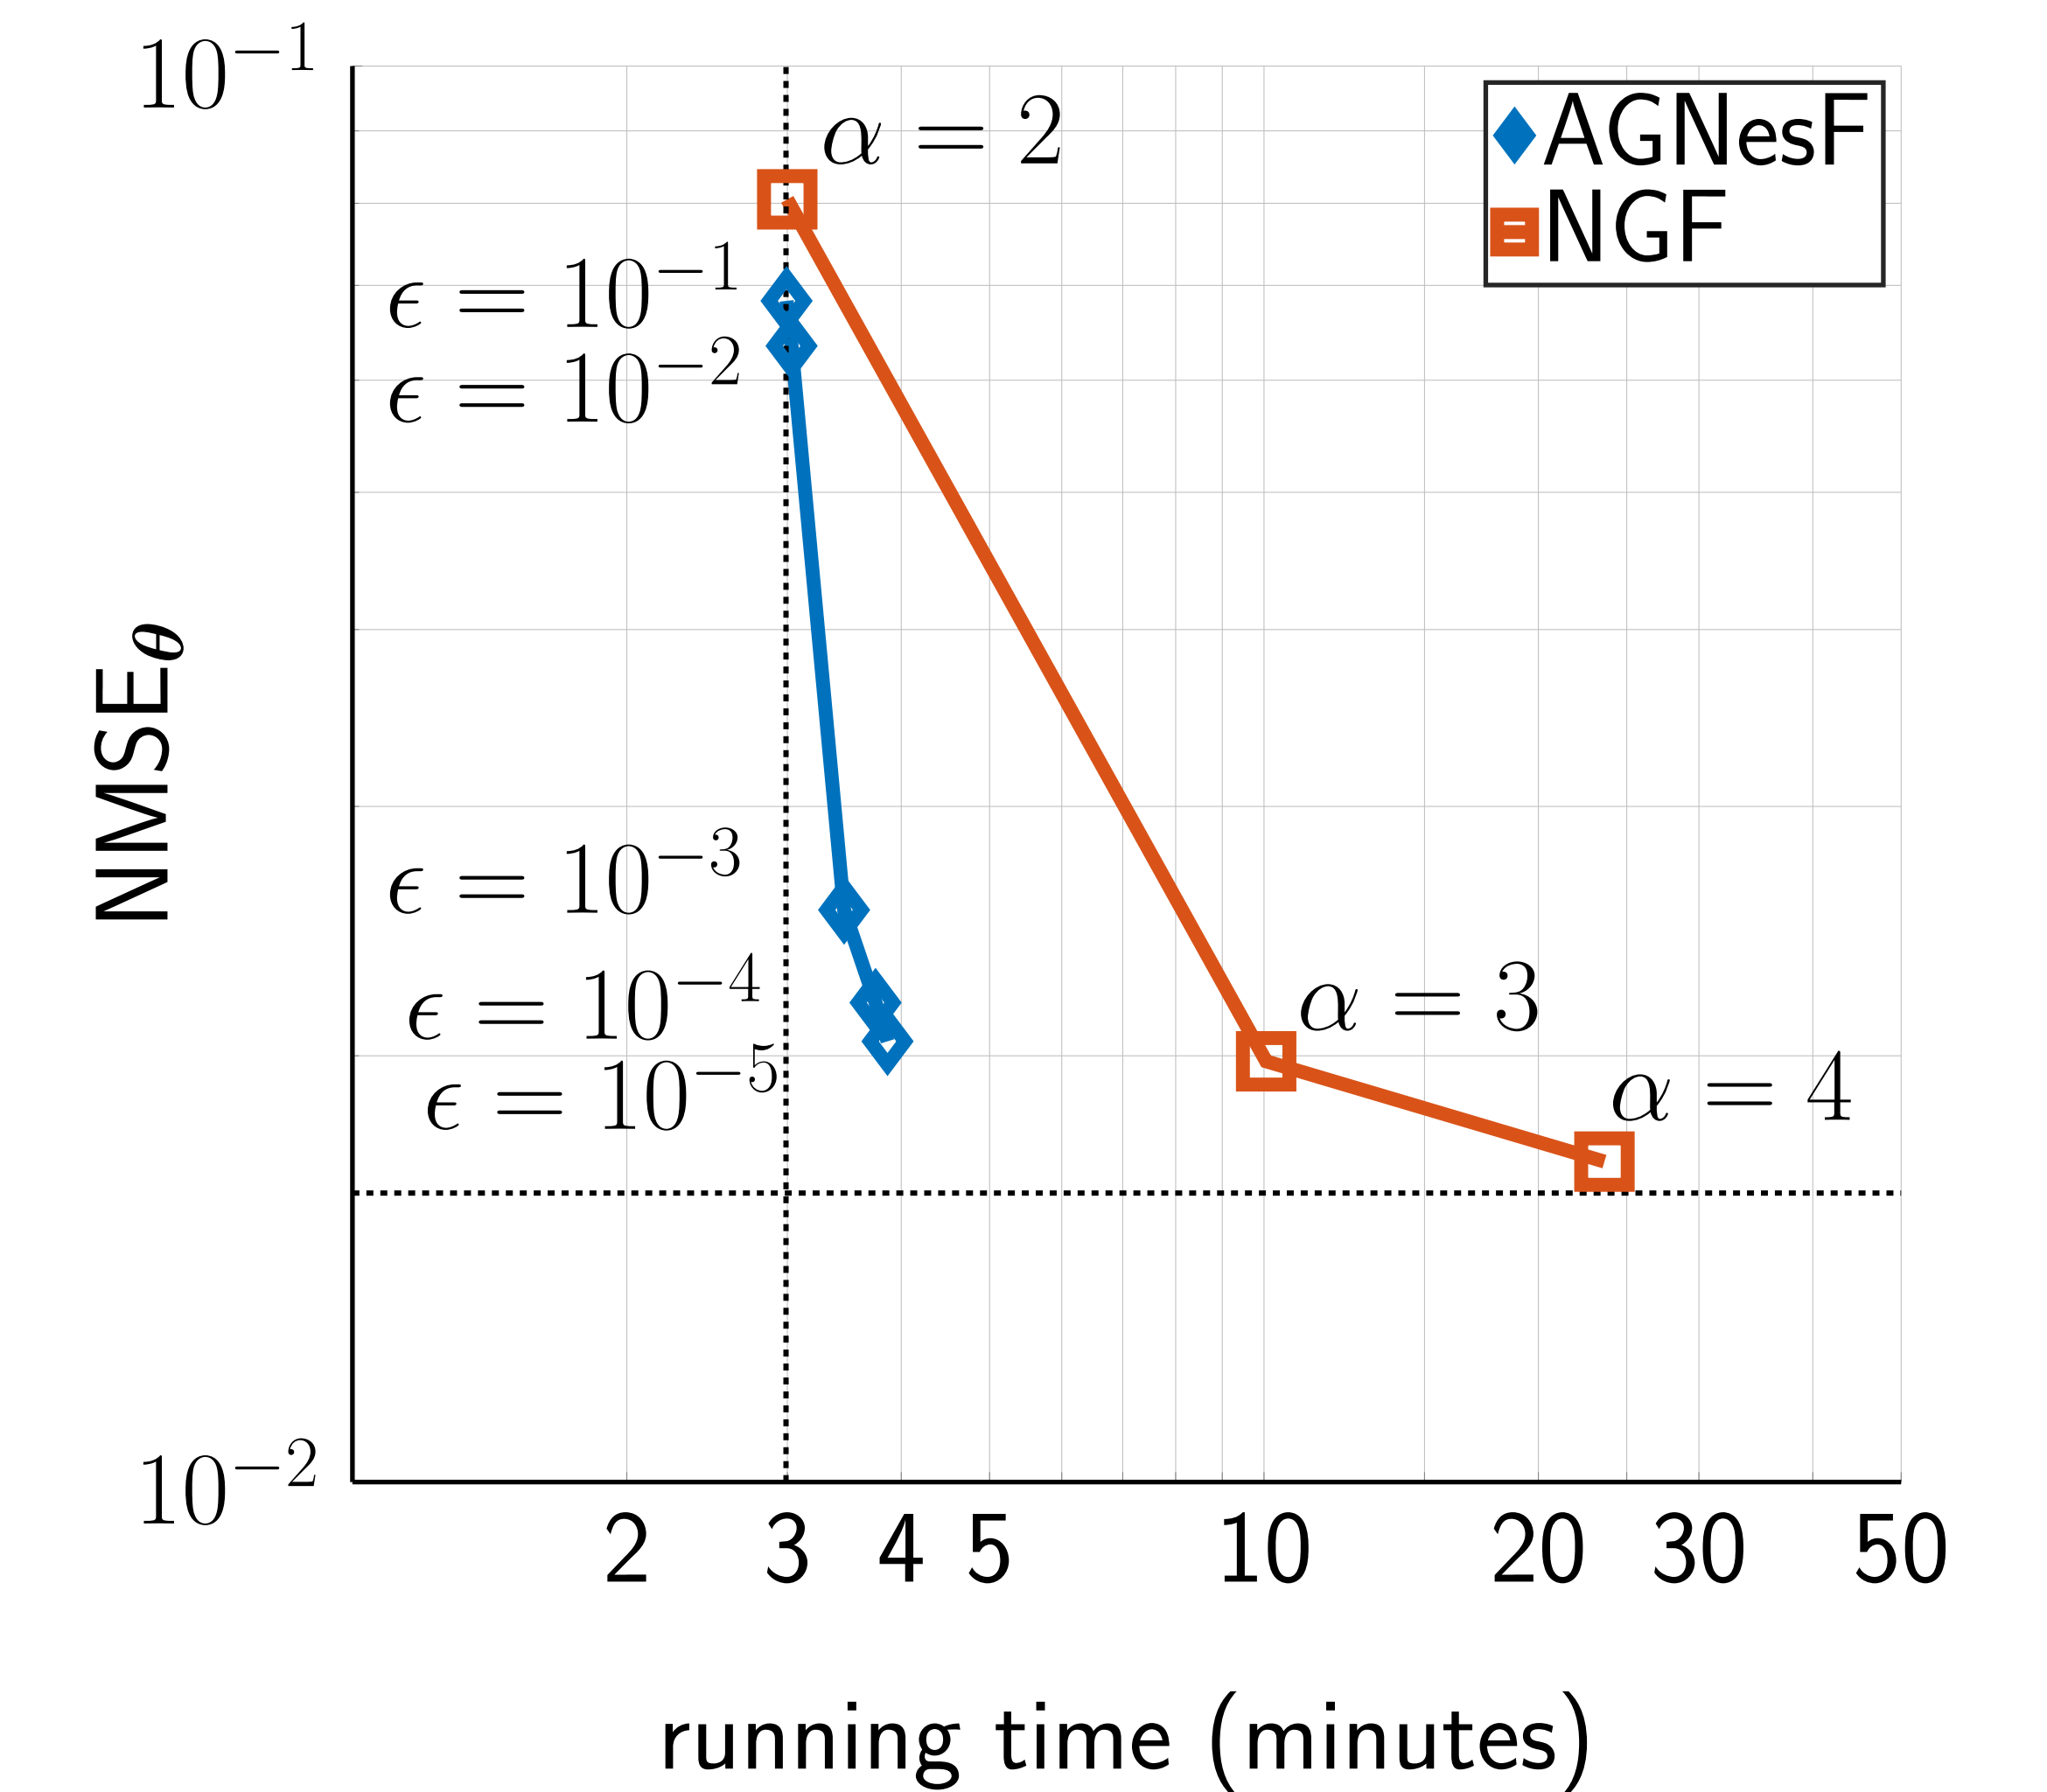

**Adaptive  $N_{\theta,t}$ .** We change  $\alpha$  over time:

- If  $\frac{\rho_t}{N_{\theta,t}} < 1 - \epsilon$ ,  

$$N_{\theta,t+1} = \alpha_{t+1}^{d_\theta} \quad \text{with} \quad \alpha_{t+1} = \max(\alpha_t - 1, \alpha_{\min}).$$
- Otherwise,  $N_{\theta,t+1} = N_{\theta,t}$ .

## Numerical Experiments

- Synthetic data of **Lorenz 63 model**.
- Estimation of  $x_t$  and  $\theta = [S, R, B]^\top$ .
- Comparison of:
  - AGNesF with  $\alpha_0 = 4$  and  $\alpha_{\min} = 2$ .
  - Nested Gaussian filter (NGF) with fixed  $\alpha$  and  $N_\theta$ .
